Declaration

I hereby declare that the work presented in this thesis is entirely original, and has been carried out by me at the **Raman** Research Institute under the auspices of the Department of Physics, Indian Institute of Science. I further declare that this has not formed the basis for the award of any degree, diploma, membership, associateship or similar title of any University or Institution.

B.Ramesh

Thesis Overview

Lack of reliable estimates of distances to most of the local dark clouds has, so far, prevented a quantitative study of their kinematics. Using a statistical approach, we have been able to extract the average spatial distribution as well as the kinematical behaviour of the local dark clouds from their measured radial velocities. For this purpose, we have obtained radial velocities for 115 southern clouds and used the data from the literature for the northern ones. The thesis mainly deals with the presentation of this new data, analysis of the new as well as the existing data and the comparison of the results with those arrived at by earlier studies.

The local clouds are found to be expanding at a speed of $\sim 4 \text{ kms}^{-1}$ which is in general agreement with the estimates from optical and HI studies. However, it is found that the kinematics of the local clouds is not described by the model proposed for the local HI gas where a ring of gas expanding from a point gets only sheared by the galactic rotation. Rather, the observed distribution of their radial velocities is best understood in terms of a model in which the local clouds are participating in circular rotation appropriate to their present positions with a small expansion also super-imposed. This possibly implies that cloud-cloud collisions are important. The spatial distribution of clouds derived using such a model is in good agreement with the local dust distribution obtained from measurements of reddening and extinction towards nearby stars. In particular, a region of size $\sim 350 \text{ pc}$ in diameter enclosing the Sun is found to be devoid of clouds. Intriguingly, most clouds in the longitude range 100° to 145° appear to have negative radial velocities implying that they are approaching us.

Two other related research efforts are also reported in the thesis: (i) Since the clouds observed are distributed over the entire longitude range and wide latitude range, the resultant database of the spectral line parameters is well suited for studying the average physical properties of the local clouds. Our investigation in this regard shows that, with respect to latitude, the medians of both the brightness temperatures of the clouds and their ^{13}CO column densities increase marginally while the median of the ^{12}CO linewidths shows clear decrease. Some explanations for these trends are given. (ii) We also mapped one of the Orion system of cometary clouds, L1616, in $J=1\rightarrow 0$ transitions of ^{12}CO and ^{13}CO with a view to estimate its mass and star formation efficiency as well as to determine if it is gravitationally bound. It is found that the distribution of the emission in the line wings shows clear evidence for mass motions. Also, the virial mass of the cloud is found to be five times the actual cloud mass determined from the ^{13}CO column density map. It is argued that this cloud has abnormal star formation efficiency and is possibly disintegrating. The morphology and the location of the cloud indicates that it is being affected by the star ϵ Orionis which is also possibly responsible for the cloud's unusual star formation efficiency.

Acknowledgements

Any endeavour, small or big, involves the understanding and support of many, their help often given over and above the call of duty. Such help in need is very sincere and without any expectation. It may be that the feeling of gratitude for such assistances is diluted by publicly expressing it. However, unless it is expressed in some form, its very existence may be cast in doubt even to oneself. For want of any better practical form of expressing it and for my own personal satisfaction, I wish to record my deep sense of indebtedness to several people who have helped me in many ways in this research endeavour.

I am very grateful to the organizers of the Joint Astronomy Programme at the Indian Institute of Science. After the course work at the Department of Physics I went to the **Raman** Research Institute for doing research, and I would like to thank the Director of **RRI** for making available to me all the facilities at RRI.

My grateful thanks are due to Narayanan, Ramesh Kumar, Devadas and Palanichamy who helped me with the observations. During the 1990-91 season when there was a shortage of hands **Rajasekar**, Lakshmy and Seetha put in extra hours to help me with my observations - I thank them for this. I also thank Sukumar and Lakshmy for their help with the telescope software, data acquisition and backup.

Several other members of the Millimeterwave Lab and the Observatory have rendered invaluable help. In particular I would like to express my gratitude to **Rengarajan**, Suresh Rao, Amudha, **Antony** Joseph, Selvamani, Chandrasekhara, Ateequlla, Ananth and Raghavendra.

At RRI, the Library and the various services offered by its staff were simply superb. I am deeply indebted to Ratnakar and other Library **staff**, especially Geetha, for their continued help over the years. Equally important was the help offered by Ramachandra Rao and Raju Varghese of the Photographic Lab.

I would like to thank Rajasekhar and Ramadurai for their help during the data reduction with **Vax 11/780** and subsequent analysis with the Sun workstation. And **Ganesan** for leaving his 286 AT with me; it was of immense help in the final stages of the thesis.

I am grateful to **Krishnamaraju** for handling all the official transactions with IISc. My grateful thanks are due to Ramasubramaniyan for typing the thesis in a very short time and '**T_EXing**' it. Writing a thesis involves many years of grind and being away from home. During this period, **RRI** was a home away from home to me. I would be failing in my duty if I did not express my sincere gratitude to the Canteen Staff.

In addition to being instrumental in me taking up the major topic of the

thesis viz. A Kinematical Study of the Local Dark Clouds, G.Srinivasan showed continued interest and concern for the project. He has put in an enormous effort in improving the thesis through his many critical reviews. Further, he had to put up with many deficiencies in me. I am indebted to him for this.

I thank my thesis supervisor V.Radhakrishnan and also G.Srinivasan, Rajaram Nityananda, T.K.Sridharan, A.A.Deshpande, Somnath Baradhvaj and R.Rama-chandran for many helpful discussions. I will truly cherish the time I had arguing with the students at RRI about various matters, both scientific and social.

Finally, I wish to express my gratitude to T.K.Sridharan whose friendship has been a great support, and to the members of my family for their understanding, support and concern.

They say: "Since men think that by the Knowledge of Brahman they become all, what, pray, was it that Brahman knew by which It became all"

This self was indeed the Brahman in the beginning. It knew itself only as "I am Brahman". And whoever among the gods had this enlightenment, also became Brahman. Now, if a man worships a deity, thinking: "He is one and I am another", he does not know. He is like an animal to the gods. As many animals serve a man, so does each man serve the gods. Even if one animal is taken away it causes anguish to the owner. Therefore it is not pleasing to the gods that men should know this.
